

Vanilla-M4 vs. silence-M4, SNR -5 dB

Vanilla4 and Silence4 achieve the exact same total exponent $-\log J^N$ at every SNR (one curve per SNR, not two overlapping ones).
 Why: both use thresholds $\{0.2, 1, 5\}$ $\rightarrow$ identical channel $P(u|H)$; silence only zeroes the rate cost, never the FC's exact information.

Vanilla-M4 vs. silence-M4, SNR 0 dB

Vanilla4 and Silence4 achieve the exact same total exponent $-\log J^N$ at every SNR (one curve per SNR, not two overlapping ones).
 Why: both use thresholds $\{0.2, 1, 5\}$ $\rightarrow$ identical channel $P(u|H)$; silence only zeroes the rate cost, never the FC's exact information.

Vanilla-M4 vs. silence-M4, SNR 5 dB

Rate

Total exponent (identical)

Normalized exponent (identical)

Vanilla4 and Silence4 achieve the exact same total exponent $-\log J^N$ at every SNR (one curve per SNR, not two overlapping ones). Why: both use thresholds $\{0.2, 1, 5\}$ -> identical channel $P(u|H)$; silence only zeroes the rate cost, never the FC's exact information.

Vanilla-M4 vs. silence-M4, SNR 10 dB

Vanilla4 and Silence4 achieve the exact same total exponent $-\log J^N$ at every SNR (one curve per SNR, not two overlapping ones).
 Why: both use thresholds $\{0.2, 1, 5\}$ $\rightarrow$ identical channel $P(u|H)$; silence only zeroes the rate cost, never the FC's exact information.
