

All SNRs: Vanilla-M4 vs. Silence-M4 -- rate, normalized exponent, and exponent vs. R

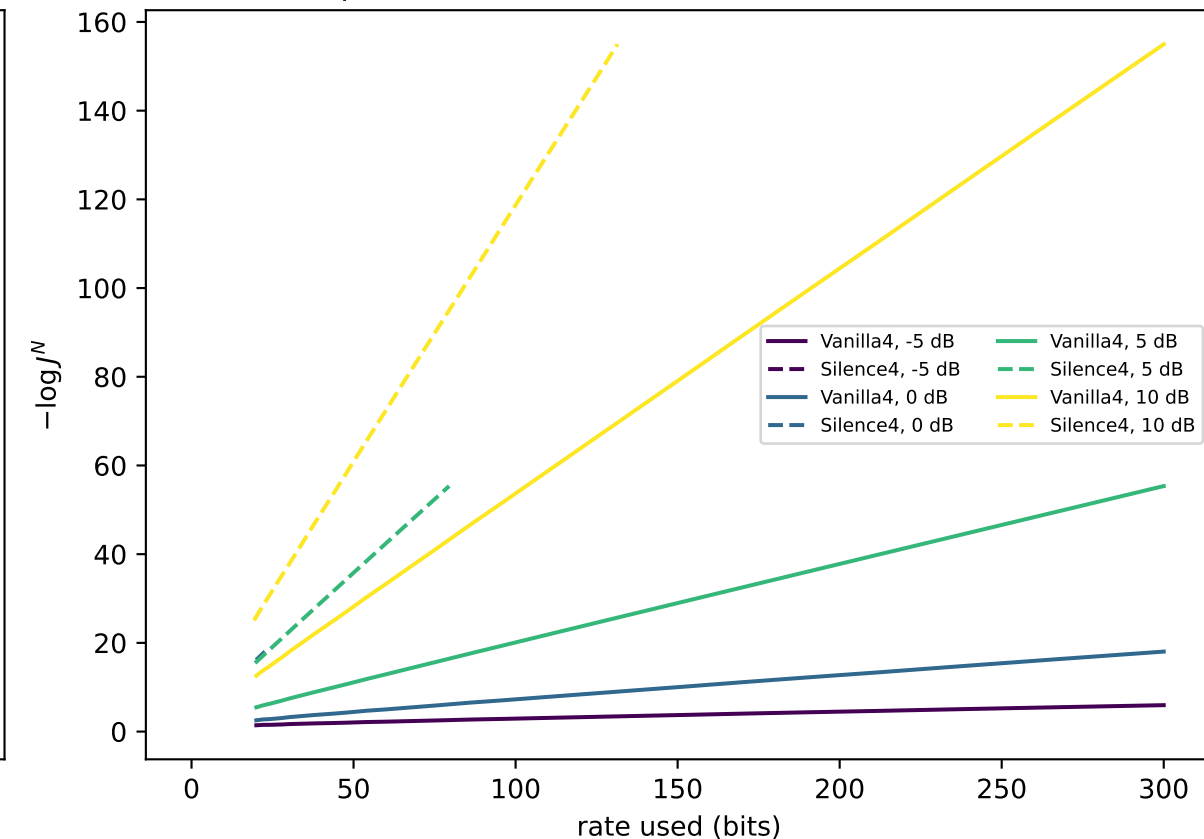

Rate (solid = Vanilla4 R=2N, dashed = Silence4 mean rate used)

Normalized exponent (identical for Vanilla4 and Silence4)

Error exponent vs. R (solid = Vanilla4, dashed = Silence4)

Vanilla4 and Silence4 achieve the exact same total exponent $-\log J^N$ at every SNR (one curve per SNR, not two overlapping ones).
Why: both use thresholds $\{0.2, 1, 5\}$ -> identical channel $P(u|H)$; silence only zeroes the rate cost, never the FC's exact information.
